Conductor-gap research: native progress

15 October 2026 — completed observations and pending work

8,000 construction trials completed across 100 prime gaps. All 2,000 same-crater map/scalar comparisons produced identical complete point/coefficient records. Timing observations are L0 and descriptive.

L0, concurrent work; descriptive CPU values. Raw source: results/orbits.jsonl

The fast square-root Vélu codomain constructor matched all 100 known direct codomains exactly. Independent PARI checks certified 15 additional floor models, including a 91-bit field with prime conductor gap 17,592,186,219,863, and ten D = −43 controls.

The small ecbench adapter control verified all six runs after a public-fixture transport bug was fixed. Both the failed and successful sessions are retained. Independent Rust replay checks factor-base scalars, relations, rank and final target recovery.

The 100-pair campaign is running: 300 IC attempts and 200 independent same-point rho attempts. No final solve rate or IC/rho speedup is reported here. Work counters include unpriced components.

Fresh-target, query-seed, coordinate-model and additional-floor replication remains pending. The 95/96-bit constructor rows were deferred after shared memory approached its 16 GiB limit. No completed 96-bit paired benchmark or general ECDLP hardness gap is claimed.

This PDF renders recorded values only. REPORT.md, results/CONDITIONS.md, the native sources, raw JSONL and certificate receipts define the evidence and accounting limits.
