Current-main merge: local verification complete

16 October 2026 · source integration record

This report records integration and test observations. The separately sealed P192 degree 50341 scientific replay continues; no mathematical admission or speed claim follows.

Source. Merge 3b7b24b1620f92d9d9c108e18f1688041a14ad2a joins published repair a5c1c39d31 with current main 3714752ee6. Its only conflict was the release workflow draft setting. The resolution retains the fully prefixed version and draft=true until binary upload, download and original-manifest checks succeed. Other upstream bytes are preserved; pushed history was not rewritten.

Fresh root gate. The required release-library test command passed at the merged source: 4148 passed, 0 failed, 117 ignored, exit 0. Recorded execution 325.17s plus separate compile 5m52s are shared-host operational durations, with no speed comparison. The isolated test binary hash is e6b0366e…ec7399; the complete hash, command, toolchain and raw log are in README.md and verification-summary.json.

Publication helpers. Nine local transport-fixture cases and ShellCheck pass after restoring the tracked sparse helper paths. Both helper sources match the tested repair; the final workflow hash is recorded in workflow-final-check.txt. No root-library source changed during shell materialization.

Retained failures. An initial bootstrap stopped on preexisting main SVG/PDF whitespace before test execution. Its complete log is compressed beside this report; the manual workflow resolution passes its scoped whitespace check. First shell checks exited 127/2 because the merge reapplied sparse checkout and removed tracked helpers from disk. Their Git blobs remained present. Initial receipts and the successful materialization/retry are both preserved; no source failure was hidden.

CI wiring. A dedicated release-assets job runs the existing shell checks on PRs and main; official publication depends on that job. This workflow-only addition leaves the tested library source unchanged.

Remaining. Current-head CI and live repaired official publication remain outstanding. v0.1.2372 still has failed checksum admission. The scientific process uses its own immutable executable and input; these library checks neither restart it nor admit its map. The diagram describes gate flow, with no comparative performance data and no changed canonical mathematical graph.
