Volcano IC: all strata, 70-vertex release checkpoint

Run 20261017T0540Z. Counted diagnostic; no admitted runtime or speedup claim.

All 51 conductor strata: measured size-64 MITM yields

Blue: relations per source trial. Orange: relations per actual oracle call. Points: native mean; bars: observed min–max.

Conductor order is ordinal on each x-axis; n is measured target attempts, not independent vertices or a confidence interval.

Run 20261017T0540Z: 70 audited vertices / 24,823 planned. All strata sampled; entire-graph distributions incomplete. One failed capsule excluded.

Graph key	Audited vertices	Planned vertices	Audited strata	Planned strata	Largest End(E) conductor
mixed	34	10070	28	28	1728
three	15	6561	9	9	6561
two	21	8192	14	14	8192

Observed: 1,120 measured attempts: 810 verified recoveries, 280 exhausted budgets, 30 watchdog timeouts. All 51 conductor strata have measured vertices; only 70 of 24,823 vertices have been audited. Stratum coverage is not complete graph coverage. Maximal sampled conductors are 8192, 6561 and 1728.

Integrity: every included standard audit receipt passes; successful/exhausted deterministic reports replayed when collected. The stopped checkpoint inventory rechecks every receipt/file hash, all 1,120 record seals, exact replay populations and ledger/queue identities. It is a receipt-binding check, not a fresh or independent solver replay. The failed three-v10-attempt-001 capsule (16 raw records) and failed audit are retained separately in the archive; they are excluded from these accepted summaries. Its record 10 combines timeout status with a checked scalar. No old record was relabeled. A watchdog recording repair is tested separately.

Yield definitions and complete stratum tables

Correction to earlier wording: the earlier reports called 301,715 source trials “attempted decompositions.” Trials include duplicate queries skipped before the oracle. Their recorded values and historical PDFs are unchanged. The new summary retains both denominators: 1,496,975 source trials and 1,383,570 actual decomposition calls, producing 42,746 relations across 700 IC reports. For these guarded classic-walk arms, calls equal trials minus repeated queries skipped. Identity skips occur before trial increment. All 420 two-summand MITM records independently agree with their lookup counters. A zero/unknown call denominator has no yield; timeout counters are never assumed zero.

The legacy field relation-yield remains a per-trial alias. Summary schema v2 adds explicit trial-relation-yield and oracle-call-relation-yield, numerator, denominator, sample counts and definitions. Global totals across distinct subgroups/bases are descriptive accounting, not a common success probability.

The tables show only size-64 projected MITM, with every conductor stratum. GAE values are lower bounds with unpriced native work. Exhausted rows are attempt costs, not successful DLP costs. Means use present observations and the explicit n; multiple vertices per stratum are sampled, not a census. Native CSV/JSON contain every arm, phase, status, range, matrix rank/dependency, memory and raw elapsed observation. Exact generator representations remain explicit and unregistered where noted; no new curve-name alias is inferred.

Protocol and provenance: projected bases 16/64 with MITM/subtraction, unchanged raw-base MITM, rho.negation, textbook BSGS and rho A/A. Two public targets per vertex, one alternating round, zero warmups, target seed 20261017, order seed 1, 4,096 source trials and a 3-second child watchdog. Actual largest prime subgroups are retained, including the 45-bit subgroup. Cold solver setup, projection and verification are charged. All original measured sessions remain byte-frozen. Source commit 9bca26ae25f480f4b2162fc03f0d4d0ff20ed3cf; complete stopped campaign, native source, queue, ledger, receipts and frozen runner are in the archive.

Host and limits: Intel Xeon Platinum 8573C, Linux x86-64, four-CPU quota, 16 GiB RAM. Release-profile ecbench hash 62023d1469010a6d6b9a85b080f261f2fce28c3c55bb26be71dc243bc01b1aee. All wall observations are unqualified. No optimized runtime comparison is admitted. This worker halted on its failed audit after 432 elapsed seconds; that invocation includes orchestration and replay, not only solver work. The historical dev checkpoint remains a separate dataset. Neither its repeated targets nor its timings are pooled here.

The full million-trial/eight-target/five-round/four-size matrix, original A–E full graph request, all-vertex completion, exact representation registry, transported-target benchmarks, composite PH, actual finite-field IC and independent implementation replay remain open. Exact embedding degrees 30,875; 3,953,777,913,734; and 2,126 exceed the implemented MOV teaching backend. This is an implementation gap, not proof that mathematical reductions do not exist. A repaired runner must pass fresh controls and completed-report matching before a separate new campaign launches. Canonical fastest-method claims are unchanged.
