Ecbench run: batched prime pair table

Session `ECBS1h4d0b9e4a02a7` started 2026-10-13 17:38 UTC. Frozen spec `specs/prime20-b64-batchtable.json` was committed at `a45880095` before execution; the clean source was `3904a4f9`. Binary SHA-256: `4c55e01badbba18a43c7b096ff42c4e701996cc5311ce708a295b3235b4db391`. Host: macOS arm64, `--cpus none --allow-busy`, L0. Eight public targets of `icv1-fp20-t727-cd198a38` used seed 20261015, one warmup and three measured rounds per arm.

Arm	Verified	Mean cold GAE	Mean setup wall
scalar table	24/24	18,633.042	243.226 µs (L0)
batched table	24/24	18,633.042	128.380 µs (L0)
rho.negation	24/24	1,148.125	—
rho A/A	24/24	1,148.125	—

The source loops imply 4,096 field inversions for the scalar table and 64 for the batched table at B=64; these are derived counts. All 128 executions verified. `../../pair-check.json` records 32/32 exact paired outputs and counted phases. `../../replay-all.json` records 96/96 identical measured replays and zero problems. Raw sealed records are at `../../sessions/prime20-b64-batchtable/records.jsonl`; the exact commands and accounting limits are in `../../REPORT.md`. Wall observations are L0 and descriptive; native work remains partly unpriced in GAE.
