At least 2000 additional prime-degree maps

Status: IN_PROGRESS. The request stays open until at least 2000 additional distinct maps are sealed and delivered.

Two fresh 1050-step walks start on the published P192/P224 models. The earlier 50-step prefix of each class is excluded by exact source, degree and monic-kernel identity.

Each sealed step passed independent kernel, codomain, exact rational curve-equation, subgroup order, and 20 public scalar-transport checks inside the dedicated executable.

This snapshot checks linked file hashes and replay receipt contents. It does not repeat the algebraic verification. All arithmetic replay is same-host and uses separate limb and polynomial code.

Evidence: PROTOCOL.md, SUMMARY.json, per-class walk.json, raw kernel/map JSON, replay.json, curves.json and per-walk exit receipts. Counts and operational phase sums are in SUMMARY.json.

The IC performance ledger remains unchanged. Canonical model graphs are updated only with archived verified findings; unfinished steps are not registered.

Additional public prime-degree maps

Campaign IN_PROGRESS; target 2000 additional distinct maps

Integrity snapshot of exact independent replay receipts; same host

p192: prime degree 2341

6 sealed steps; 6 old maps excluded; 0 additional

Bar: additional independently verified maps, target 1000 per class

p224: prime degree 1117

19 sealed steps; 19 old maps excluded; 0 additional

Bar: additional independently verified maps, target 1000 per class

One Frobenius eigenline per step; coverage PARTIAL; two prime degrees

Proposed remaining steps are excluded from the verified count.
