Photographed-curve restart: results and limits

Fresh frozen inputs; no historical results pooled. Snapshot **2026-10-17T14:50:43.503Z**. The full selected rational 2-component has 46 curves and 90 directed maps, across five levels (1/3/6/12/24).

Exact field and source model	p=72057980207847001; a=18456521102804593; b=19958176276690439
Curve order / point order	72057979853368804 / 18014494963342201, on every transported fixture
Workload and randomness	10 generators × 10 uniform paired nonzero k values; 100 problems/curve. Linux getrandom, unbiased rejection. Answers are excluded from solver input.
Verified native solves in this snapshot	Rho 4600/4600; BSGS 3297/4600. Workers continue; partial coverage is shown, never imputed.
IC diagnostics / complete recovery	14720 actual GB systems, including 9200 setup probes, 4600 targets and 920 planted controls; all replayed in Singular. Random setup yield 0/9200; target yield 0/4600; full recoveries 0.

What the measured spread means

All 4600 rho cases are verified. Across individual cases the collision counts vary widely, while the ratio of largest to smallest 100-case curve mean is 1.246519. This descriptive ratio is not a hardness or speedup claim.

All 4600 target GB probes used exactly **217410 counted field multiplications**, while elapsed time ranged from 11.5197 to 266.014 ms. All 45000 instrumented map evaluations used 174 multiplications for each P/Q pair. Timing differences with identical arithmetic counts do not establish a hardness difference. This shared four-CPU host ran two rho and two 4-GiB BSGS workers concurrently; no isolation or fastest-reference claim is earned.

For every observed paired key, BSGS online operation counts agree across generators and curves: **verified**. The search identity is floor(k/m) online giant steps, with m=2^27; table construction is separate. Rho's coordinate-based partition changes after transport and its collision time is random, so its operation spread does not by itself rank intrinsic group hardness. Every map has degree 2, coprime to the prime subgroup order; every nonzero transported P and Q retains that exact order.

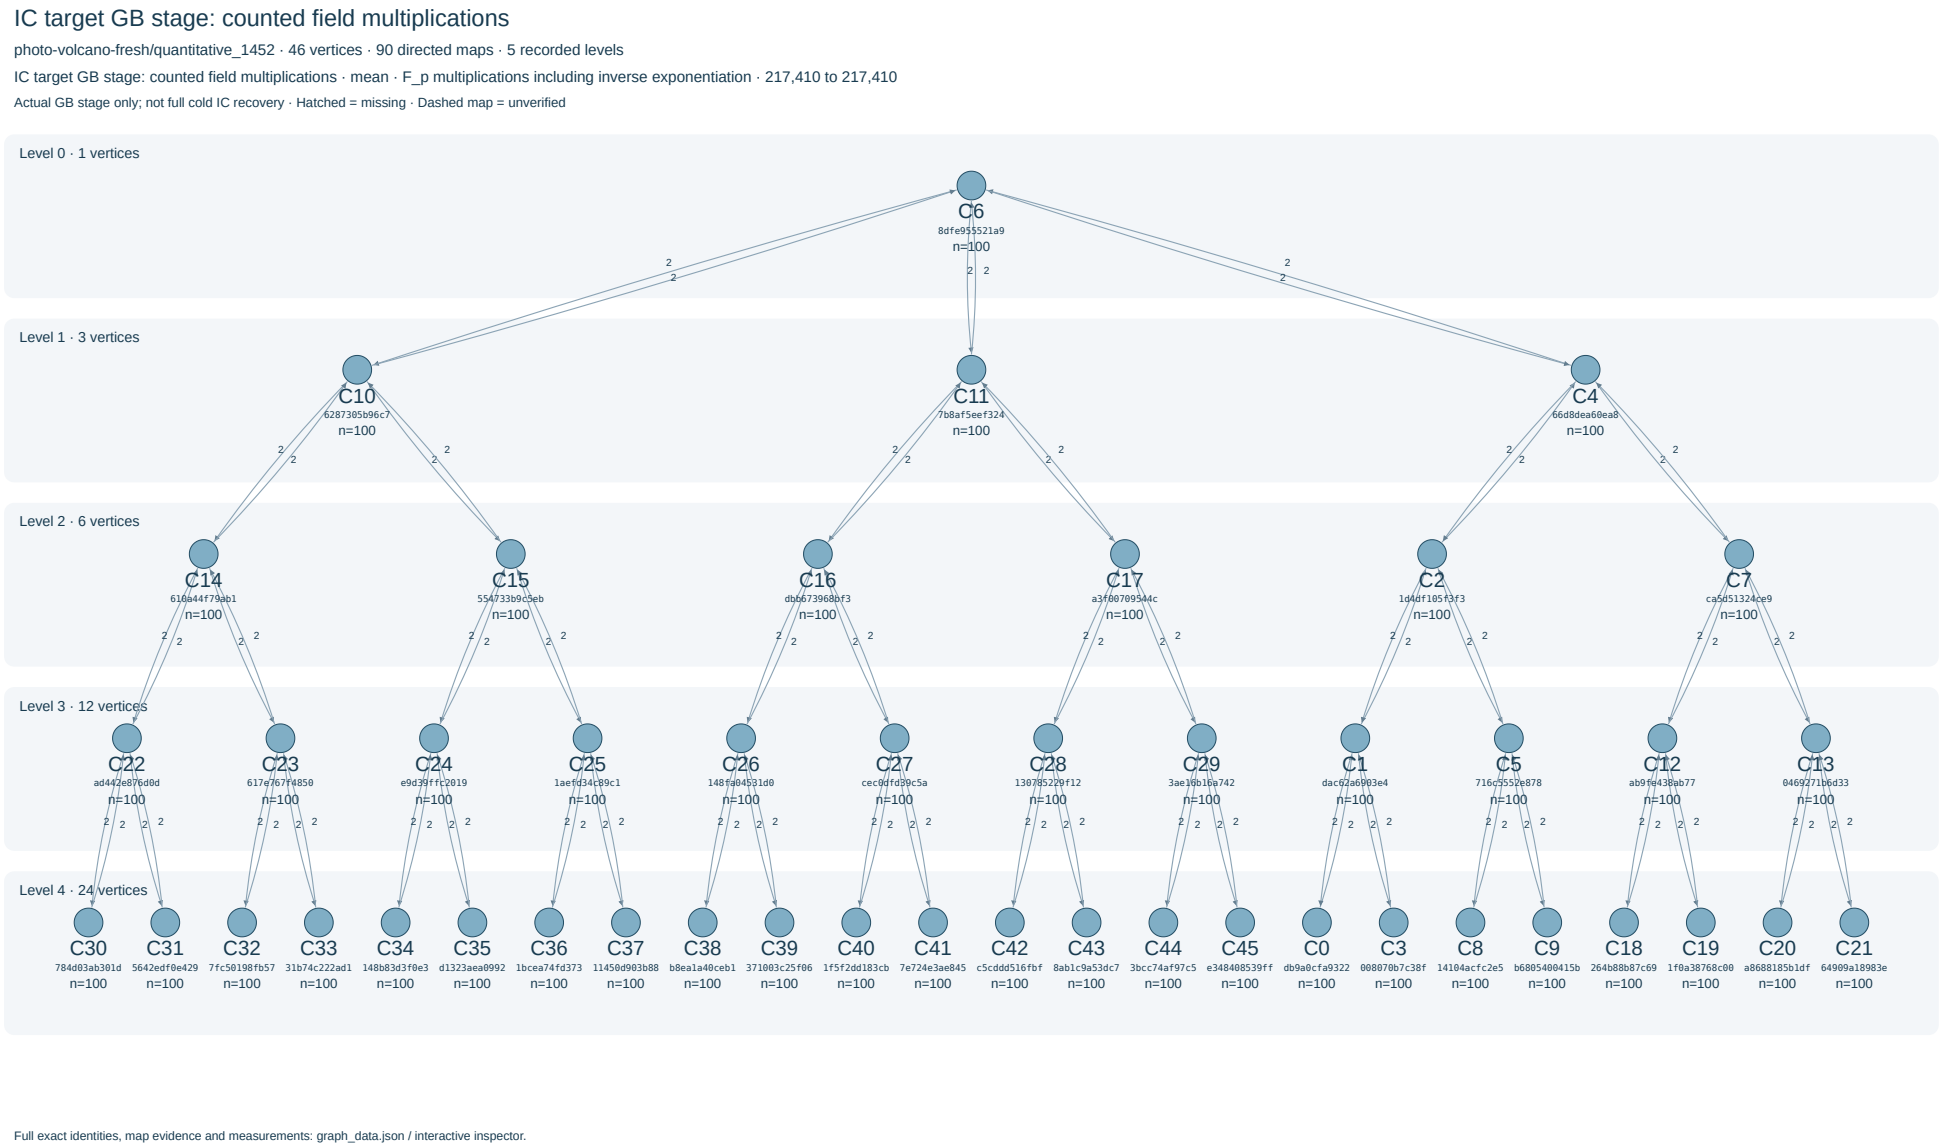

Scope and remaining work

IC uses 12 unknown-log factor-base sign orbits per generator, actual Semaev f3 plus two degree-12 factor polynomials, and 20 random setup trials per generator/curve. Its target Hilbert cutoff is 13, temporary accumulator maximum 23, processed-pair sugar maximum 26; these definitions differ. The audited strict signed two-sum support has only 288 nonzero points per factor base. Transported probes preserve relations and are not independent yield samples. A bounded zero-yield run is not an impossibility proof. A planted full-rank GB-to-linear-algebra control passes separately and adds no random-corpus recoveries.

Full native completion, successful random-corpus IC recovery, rho/BSGS field counters, full event streams, matched repeated timing and an external fastest-tool comparison remain open. Setup/query/verification/destruction and resources are retained privately; these graphs are descriptive stage views, not cold-cost or speed ratios. No complete private archive export is claimed.

IC target GB stage: counted field multiplications

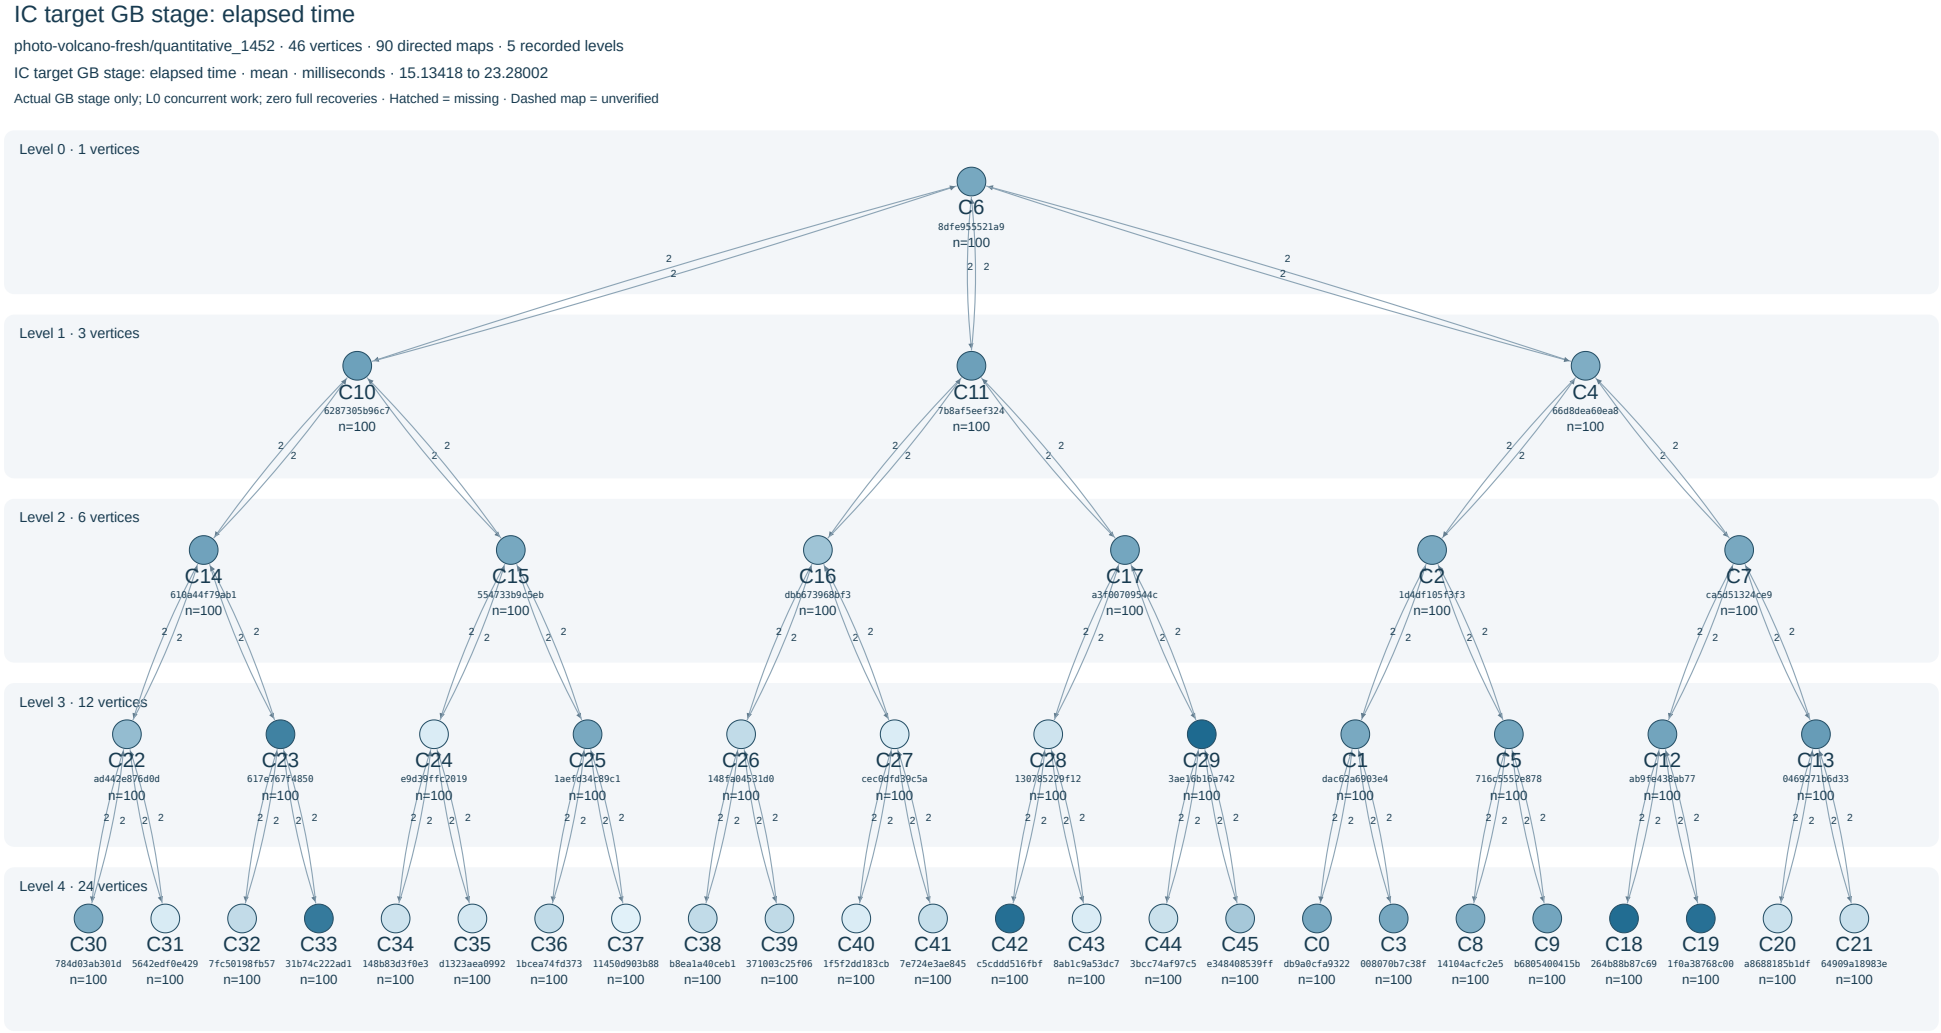

Actual GB stage only; not full cold IC recovery. Unit: F_p multiplications including inverse exponentiation. Node n is the actual measured case count; colors share one range across all five levels. 100 target probes per curve, no full IC recoveries.

Fresh fixture SHA-256: 980d931ce1a804684b160bdab9b213b87688ab9100f0cdf1cd14c390e809acb8. Exact graph and per-node min/mean/max: ic_operations/graph_data.json.

IC target GB stage: elapsed time

Actual GB stage only; L0 concurrent work; zero full recoveries. Unit: milliseconds. Node n is the actual measured case count; colors share one range across all five levels. 100 target probes per curve, no full IC recoveries.

Fresh fixture SHA-256: 980d931ce1a804684b160bdab9b213b87688ab9100f0cdf1cd14c390e809acb8. Exact graph and per-node min/mean/max: ic_wall/graph_data.json.

Fully paired rho problems at this snapshot

Each row is the same transported problem and paired walk seed on all 46 curves. This is an operation-count sample across curves, not 46 independent repeated timing runs.

Reproduce, inspect and retain

Source: source/quantitative_report.mjs, source/measurement_stats.mjs and the multilevel diagram skill. The source-linked topology report contains exact curve/map validation. Native backend commit: b7352eec52676b7b82a220ba296661e8ba878915. Shortlist commit: ef18058588077ef805c55c5dc25140b6bde2046b. Per-curve and per-problem JSON/CSV retain population, min/mean/max and missing values. IC per-problem summaries cover all 100 targets over all 46 curves; map summaries cover all 90 directed edges and 100 instances.

Raw private sources: runs/rho, runs/bsgs, runs/ic; data/map_measurements.jsonl. All attempts and input randomness remain local. Public replay inputs omit expected/recovered scalars and raw RNG journals. The public polynomial-system archive exports only mathematical systems, returned bases, factor-base points and aggregate diagnostic metrics. Independent audit: validation/singular_audit.json. Positive control: validation/ic_full_pipeline_control.json. Snapshot verification: validation/checkpoint_01_verification.json.

Host: Intel Xeon Platinum 8573C, Linux x86-64, four-CPU cgroup quota, 16 GiB memory, no GPU; L0 concurrent timing. Unmodified native group/BSGS/rho tests pass 376415/2063/134 checks. CMake, Cargo and Conductor are unavailable; GCC direct build succeeds. No whole-Rust-library check pass is claimed.

Canonical curves and progress scoreboards retain their prior claims: this fresh partial run adds no admitted performance or boundary promotion. The earlier frozen report snapshots remain immutable. This run's benchmark mirror contains identical reports and visuals.
