Bounded structural run: torsion fibers

2026-10-12T19:47Z · work item T-2070 · base commit `e3090cbc98c657106fef10020da8ccc19be49a3f`

The frozen census scanned all 1,014 curves specified by `PROTOCOL.md`: primes $p \le 199$ with $p \equiv 1 \bmod 3$, and all nonsquare b in $y^2 = x^3 + b$. Direct point enumeration and quadratic-character counts agreed in every cell; every trace passed the Hasse check. There were 349 prime-order rows. The named F_{13} map check counted 19 rational points on each side, 19 distinct images, and 361/361 ordered-pair homomorphism matches.

The runs used native Rust (`rustc 1.93.1`, Homebrew arm64), single process in a local interactive workspace. No host isolation or timing inference is claimed. Both commands exited 0; there were no failed or timed-out cells. Raw records: `census.tsv`, `summary.tsv`, `map_check.txt` in the parent study. The source and output hashes are in this run's `README.md`.

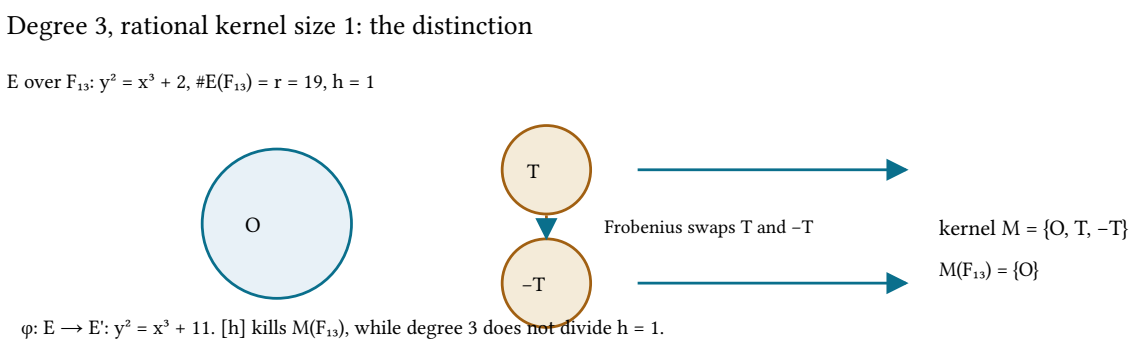

Figure 1: The named map-control fiber.

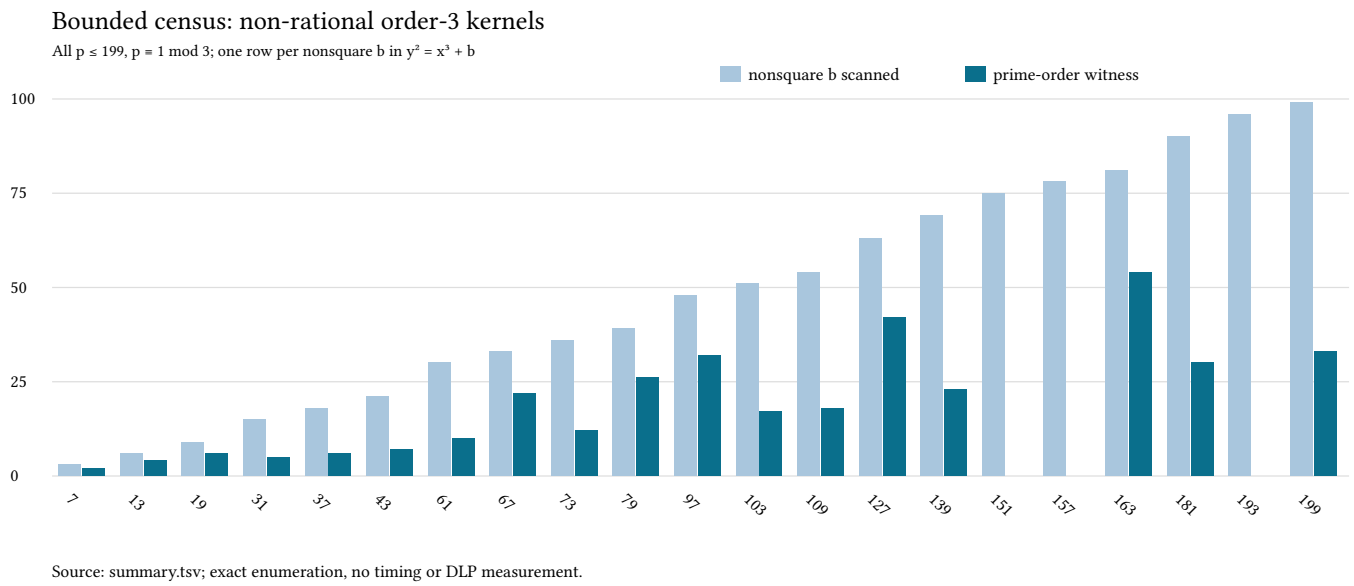

Figure 2: Exact census populations by base prime.

The figure compares exact population counts, not algorithm costs. There was no target-logarithm run, matched rho run, or end-to-end S value.
