V3 run report: balanced-order complete CPU comparison

2026-10-13 · frozen V3 remediation · 640/640 measured answers checked

V3 balanced source, destination and duplicate rho execution order across the eight targets and five measured rounds. The duplicate rho A/A CPU ratios were 0.810, 0.918, 0.819 and 0.824, all inside the frozen 0.8–1.25 band. Direct complete-CPU transport/rho ratios were 3.449, 9.789, 25.459 and 81.820 at subgroup orders 103, 439, 1,613 and 6,427. Transport/source ratios were 1.043, 1.028, 1.058 and 0.975, all with paired target intervals containing 1.

Complete cold thread-CPU work versus matched negation rho

Four non-isomorphic degree-three pairs; eight public targets and five measured rounds per size. Bars use a $\log_2$ axis: one bit of ratio is 0.61 inches. Exact values and paired target intervals are in `summary-v3.tsv`.

■ source relations · ■ destination relations. All 320 V3 relation records recovered and independently checked their scalars. Rho is 1× on this axis. A/A thread-CPU ratios were 0.810–0.918; shared-host wall timing failed its noise control. This is an L0 local CPU observation and is not an admitted wall-clock speed claim.

The independent Rust checker reconstructed all 384 relation records including warmups, verified every scalar, and checked the phase partitions. The same-host replay matched every deterministic row. Shared-host L0 CPU timing does not meet the repository's L2 wall or independent-host gates. Full records, input identities and commands are linked in `REPORT.md`.
