Official isogeny release: failed byte admission

v0.1.2372 · run38873645089 · 16 October 2026

This report records a release engineering observation. The separately sealed P192/50341 scientific profile continues; no mathematical frontier or speed claim changes.

Evidence: workflow38873645089, immutable action cede87f, exact digests in verification-summary.json.

Observed. All 12 ReleaseMe jobs report success, and tag v0.1.2372 resolves to built source 3714752ee6a9686e0fce79cb308423d9fd09cde9. All four downloaded isogeny archives fail the published checksum manifest; their hashes match GitHub asset digests. No failed-checksum archive was extracted or executed.

Exact cause. The original macOS CI archive matches the manifest (31916732…de258f). UTF8 decoding/re-encoding reproduces the public corrupt asset hash (da8b8e69…051b7a) exactly. The pinned ReleaseMe upload source reads files as UTF8. Full hashes, original source and raw headers are retained beside this report.

Native control. After checksum validation, the original CI macOS executable reports source 3714752, dirty=false. Public P192 degree 13 construction and fresh independent replay both exit0; both eigenline maps pass kernel, codomain, exact map and subgroup checks, with 20 scalar transports per map. This validates the pre-publication payload, with no performance comparison.

Repair. ReleaseMe creates a draft. A shell helper validates the local manifest, uploads files as bytes, downloads into a fresh directory, binds the downloaded manifest to the original and checks all hashes before publishing the draft as latest. Any failure leaves the draft; existing assets refuse overwrite.

Local checks. Nine transport-fixture cases pass: high-byte gzip/zip roundtrip, corrupted download, changed manifest, upload/download/publication failure, wrong local checksum, existing output and existing assets. Shell syntax, ShellCheck and workflow YAML wiring pass. No Rust or Python source changed; earlier source gates remain 4148 root-library and 94 tool tests passed.

Remaining. The repaired workflow has not executed. Official delivery still requires current-head CI, live downloaded-byte verification and a native control on the released executable. v0.1.2372 remains failed checksum admission. Canonical curves, seasons, scores and mathematical graphs are unchanged. The diagram represents custody paths; there is no performance data series.
