A20: the folded build's streams written a line at a time (smoke only)

Candidate and smoke, no exploration. `LineStream` (`line-streams-on-a19.patch`, one commit on A19's candidate):

- each partition stream keeps a 64-byte line in L1;
- full lines go out with non-temporal stores;
- the order, and so the table, is unchanged.

Tests: 207 passed (`koblitz_index_calculus`, `koblitz_fast`).

Smoke: two isolated processes per arm at 2^44.3 and at 2^47.2 (`smoke.tsv`). The builds overlap; there is no visible gain, so it is not pursued.

Probable cause, not measured: the append is bound by first-touching 45–75 MB of fresh stream memory a build, not by line traffic.

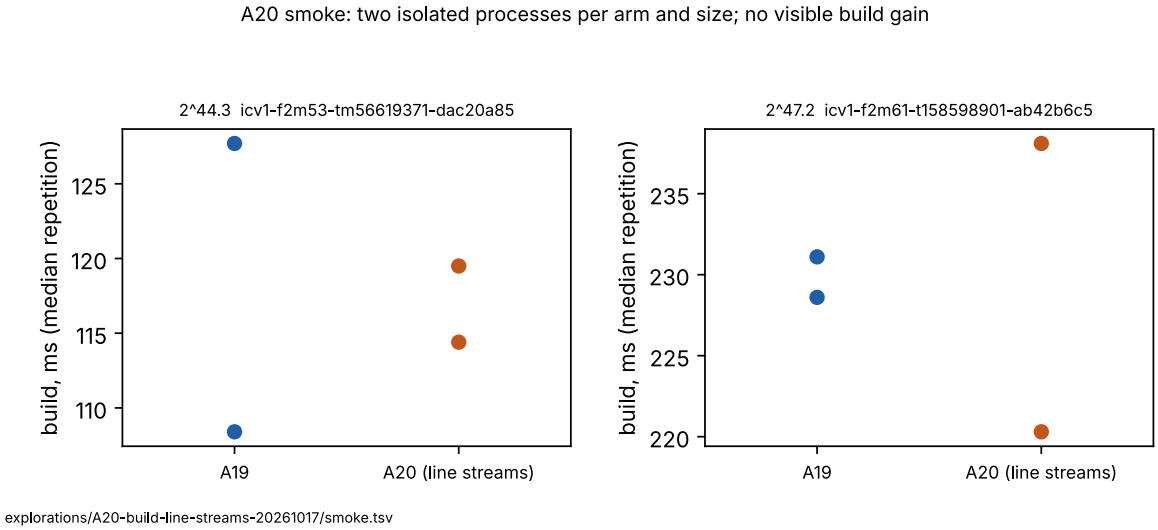

Figure 1: Each process's build time (median repetition), A19 against A20. Values from `smoke.tsv`.
