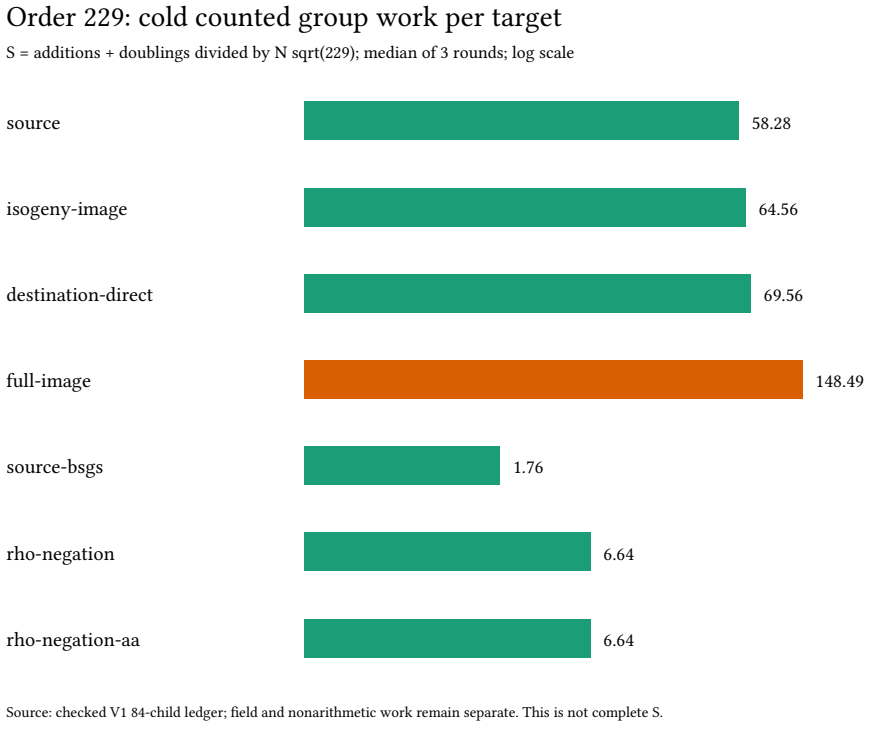
V1 portable-count derivation run

2026-10-15 23:29 UTC · Darwin arm64, shared L0. One deterministic native count derivation read the immutable order-229 run and independent replay. It checked all 84 arm-round-prefix records and all 1,785 verified scalar outputs. Exit code was zero; stderr was empty. Source, binary and input digests and exact command are in `FREEZE_V1.json` and `REPORT.md`.


$S_{\text{group}} = \frac{\text{adds} + \text{doubles}}{N\sqrt{229}}$ is a counted-group lower bound. Map field work, table/hash operations, row arithmetic and process overhead do not yet have a pinned conversion. The graph shows N=64 medians of three complete cold children per arm; bar lengths are log transformed and exact values appear beside them. The source result report holds every count axis and matched ratio.
