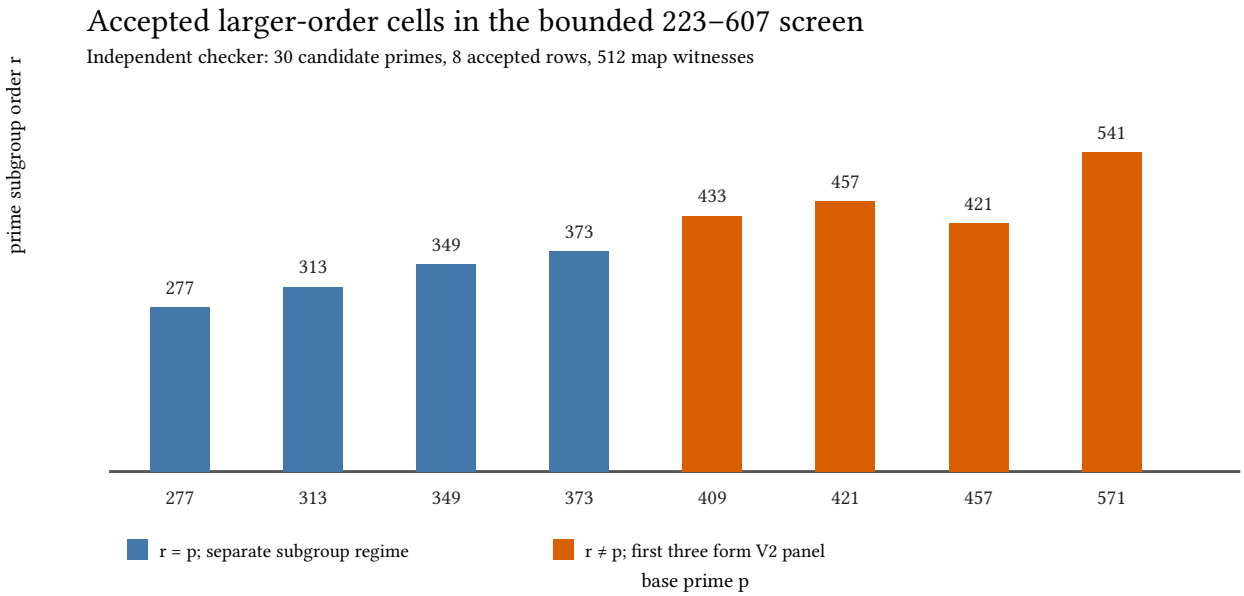
V1 bounded larger-order screen run

2026-10-15 23:29 UTC · Darwin arm64, shared L0. The native screen processed all 30 eligible primes in the frozen 223–607 range. Eight different-j rows passed the algebraic predicates and 64 seeded map witnesses each; a separate Rust implementation checked 512/512 map witnesses, group orders and subgroup factors. Both processes exited zero with empty stderr. `SCREEN_V1.jsonl`, `SCREEN_CHECK_V1.json` and `FREEZE_V1.json` hold records, exact commands and hashes.


The bars display every accepted subgroup order. Blue means $r = p$; orange means $r \neq p$. These are construction observations; this run did not include new target solves or method timing. The post-screen prime-to-characteristic selection is separately versioned in `PANEL_PROTOCOL_V2.md`.
