Five-order missing-price sensitivity run

2026-10-16 01:53 UTC · Darwin arm64 shared host. The source and binary were frozen before execution; their SHA-256 hashes and the five input run hashes are in `sensitivity_five/RUN_SPEC_V1.json`. The native derivation checked 420 child records and 8,925 scalar outputs against independent replay receipts, and all group totals against the five-order trend. Its first 48 rows and four older N64 summaries were unchanged from V1. Sixty matched rows were emitted.

The graph plots N64 median extra omitted rho group-addition equivalents per observed rho step required to tie the full-image counted lower bound, setting all omitted full-image work to zero. At order 1,201 the median was 1,390.865, with three-round range 1,266.482–1,575.602. This is a price threshold, not a measured primitive price or complete portable cost. The source-linked `REPORT.md` and `sensitivity_five/RUN.md` contain commands, hashes, values, and limits.
