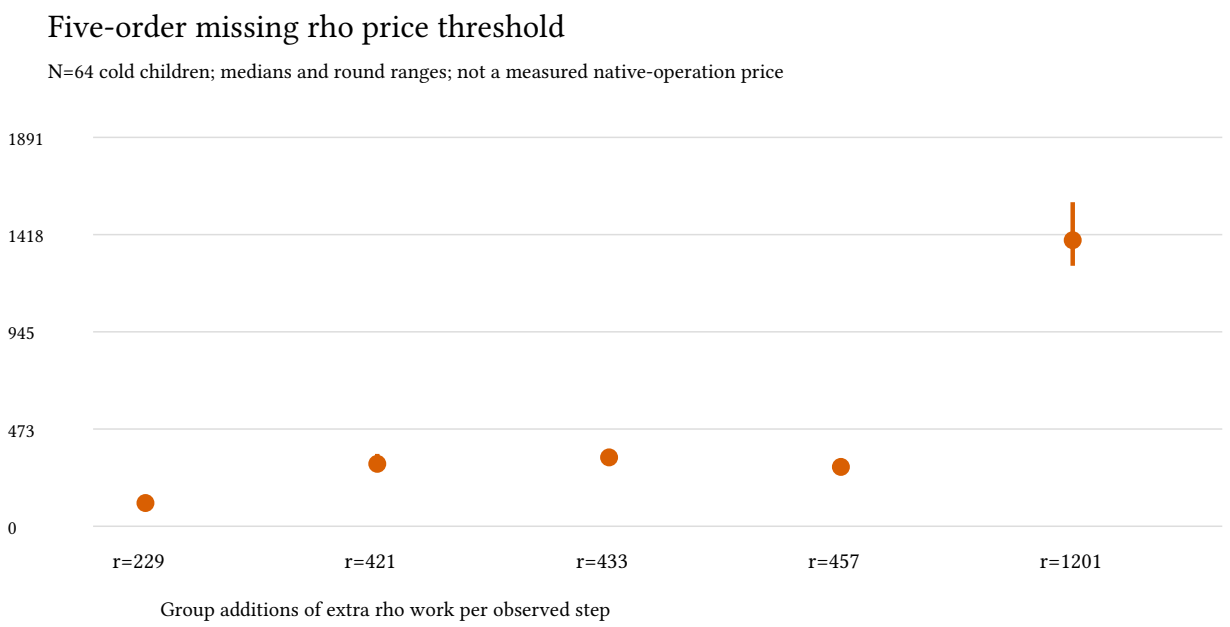
Five-order missing-price result

The frozen native analyzer rederived 60 matched threshold rows from independently replayed complete-solve records. At 64 public targets, median extra omitted rho group-addition equivalents per observed step needed to tie the full-image **group-count lower bound** were 112.973, 303.573, 334.844, 288.595 and 1,390.865 at orders 229, 421, 433, 457 and 1,201. The order-1,201 three-round minimum and maximum were 1,266.482 and 1,575.602. All historical 48 rows were unchanged.



This threshold assumes every omitted full-image operation costs zero; it is neither an observed rho primitive price nor a complete portable addition-equivalent `S`. The complete-price protocol still requires disjoint counts and host-class calibration. Exact inputs, commands, output hashes and the 60-row JSON are linked from `REPORT.md` and `sensitivity_five/RESULTS.md`. The five field primes and cofactors vary; no exponent or end-to-end speed ratio is inferred.
