Native quintic predicates — bounded evidence

Native exact quintic squarefree component, not a complete generalized rootfinding algorithm. Requested qualified8x end-to-end goal remains open.

Two frozen workers passed:20fields each,12 supplied quintics per field, three alternating internal method rounds. Both seeds and full-width generator frozen before timing. Inputs, raw stdout/stderr, process and registration records are in raw/.

Unit: internal predicate seconds; graph ratios are native jq medians from three recorded rounds. Host: managed Linux x86_64, one CPU and4GiB worker budget. No qualified isolation, A/A or confidence interval. Values are descriptive.

Native controls:4,392 exhaustive monic squarefree cases;4,392 support cases;1,024 supplemental odd-extension monics;336 repeated nonrational-quadratic cases. All passed. A preparation old-binary control output is quarantined and not counted.

The immutable original all-roots gate is unchanged. F4/F5/F6 baseline, hard coupled searches, complete root extraction, novelty and full Lean certification remain unresolved. Several cases regress; do not multiply stage ratios into a claimed pipeline gain.

Hypothesis follow-up: cold full-support recurrence plus complete extraction and A/A on new seeds; separately prove and test conditional repeated-factor reduction to cubic or quadratic support without discarding squarefree branches.
